

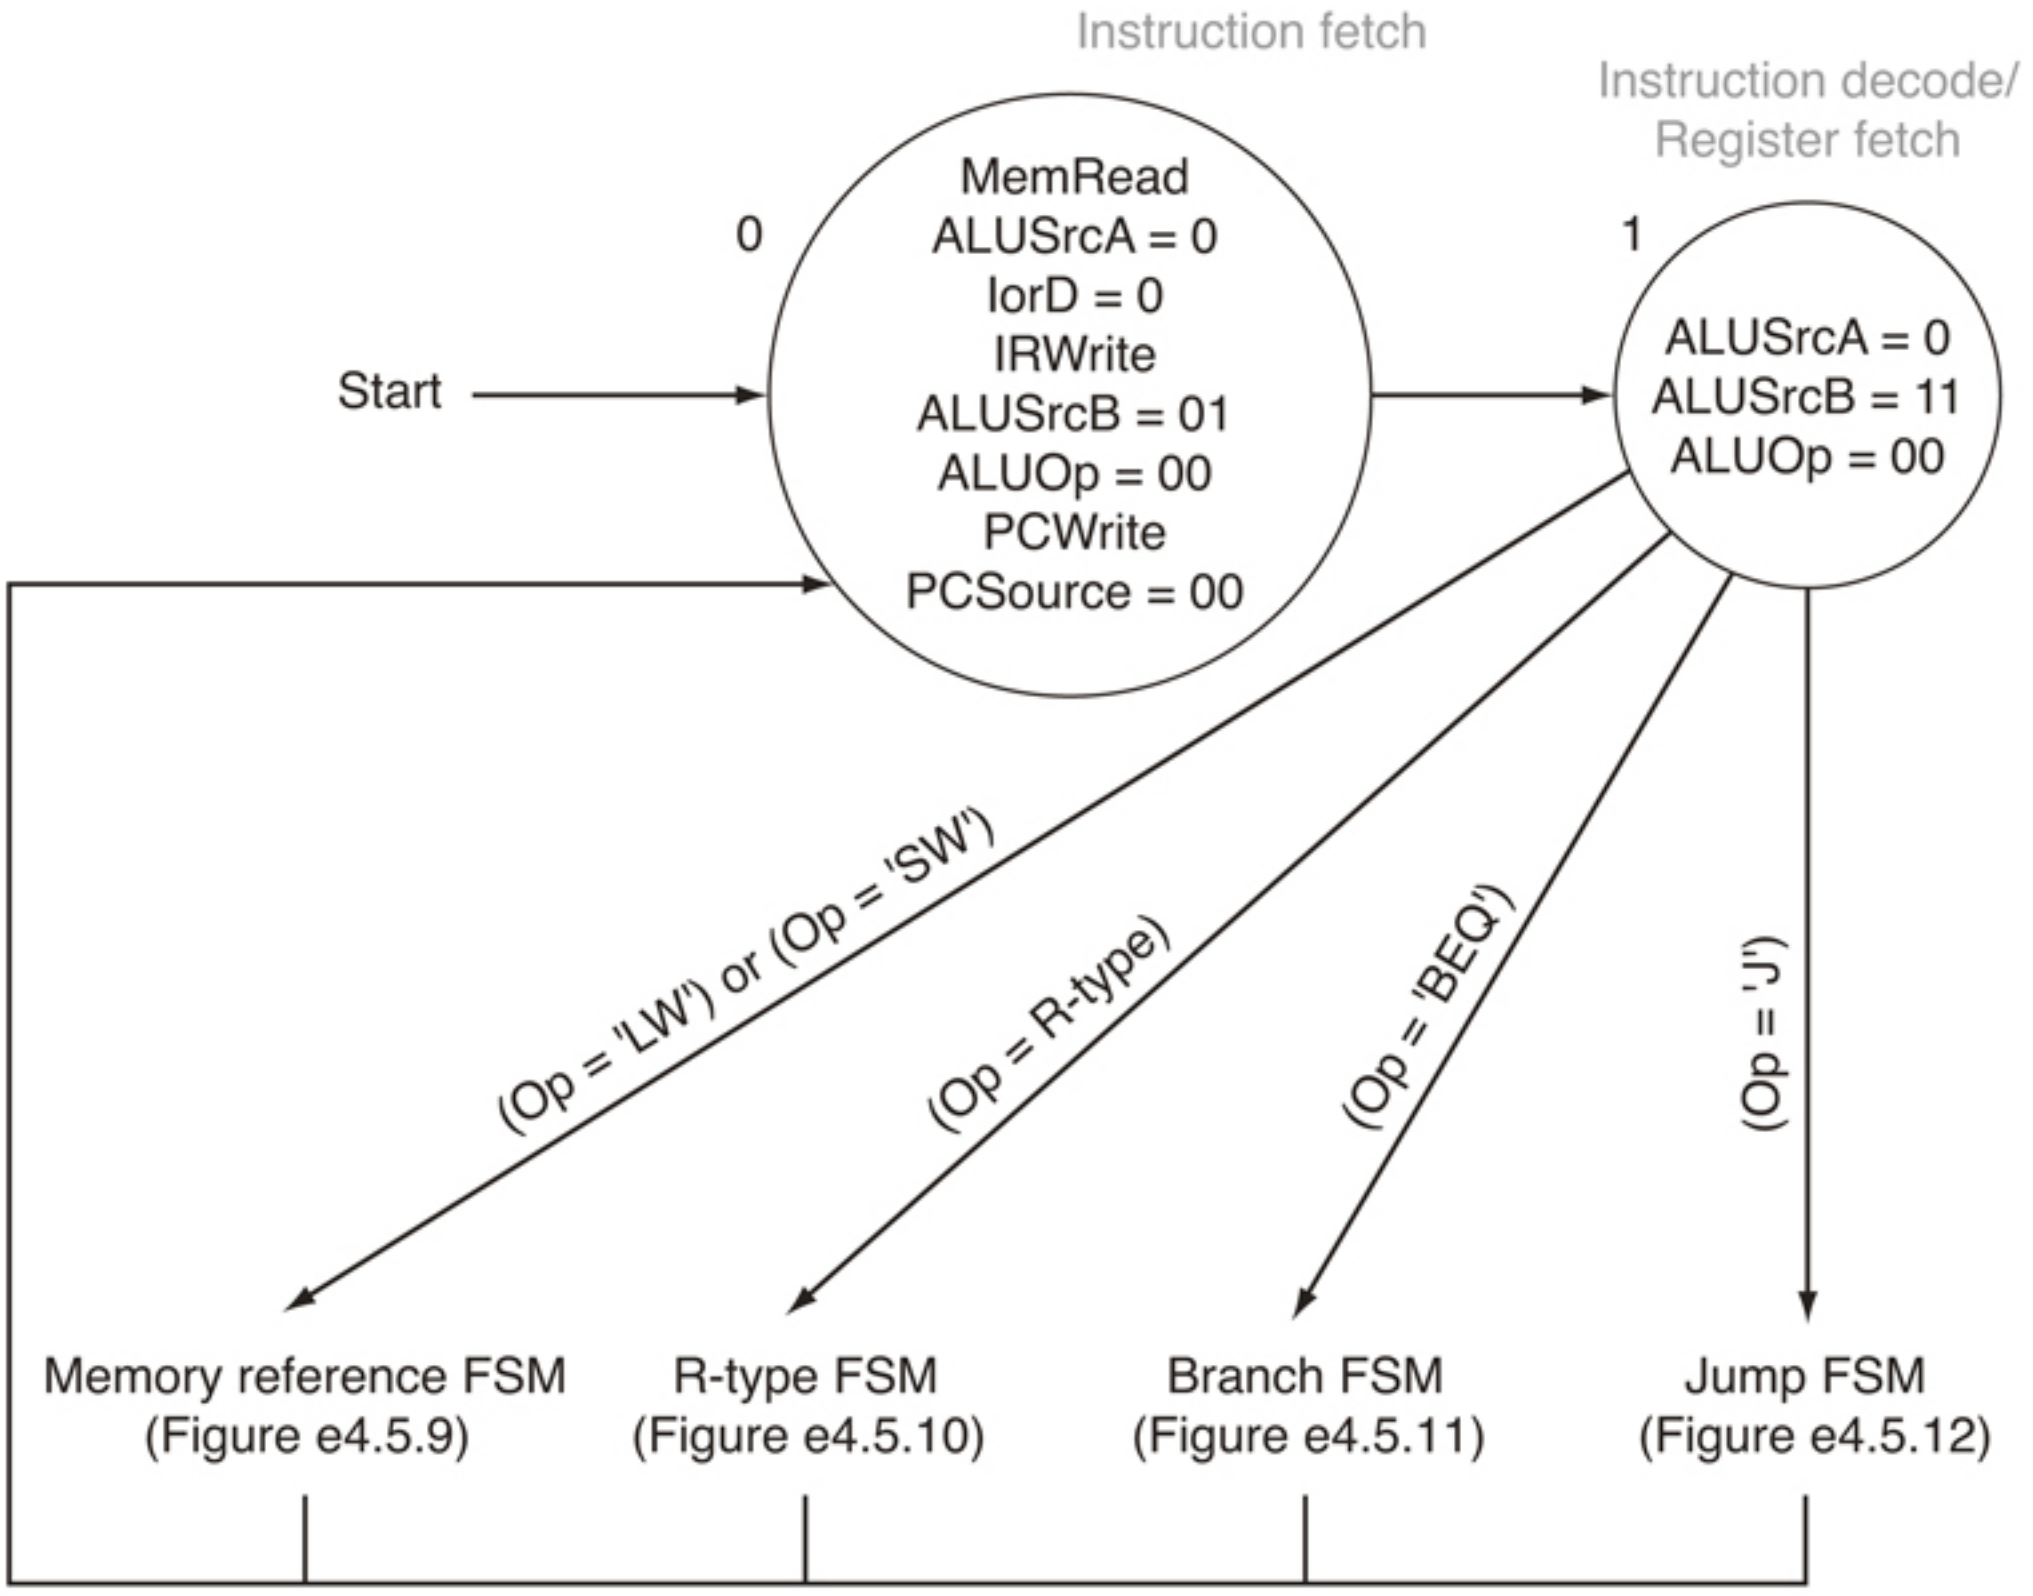

**FIGURE e4.5.8** The instruction fetch and decode portion of every instruction is identical. These states correspond to the top box in the abstract finite-state machine in Figure e4.5.7. In the first state we assert two signals to cause the memory to read an instruction and write it into the Instruction register (MemRead and IRWrite), and we set IorD to 0 to choose the PC as the address source. The signals ALUSrcA, ALUSrcB, ALUOp, PCWrite, and PCSource are set to compute PC + 4 and store it into the PC. (It will also be stored into ALUOut, but never used from there.) In the next state, we compute the branch target address by setting ALUSrcB to 11 (causing the shifted and sign-extended lower 16 bits of the IR to be sent to the ALU), setting ALUSrcA to 0 and ALUOp to 00; we store the result in the ALUOut register, which is written on every cycle. There are four next states that depend on the class of the instruction, which is known during this state. The control unit input, called Op, is used to determine which of these arcs to follow. Remember that all signals not explicitly asserted are deasserted; this is particularly important for signals that control writes. For multiplexor controls, lack of a specific setting indicates that we do not care about the setting of the multiplexor.
